*CAN THE TEMPO
BE
EXACTLY DOUBLED ?*

Erica Bisesi, Irene Gratton & G. Bruno Vicario

Aims

Research questions:

- Does an optimal tempo exist in music?
- Does an unambiguous representation of slow and fast tempo exist, with respect to a given tempo?
- Can the musical tempo be exactly reproduced?
- Can the musical tempo be exactly doubled?
- Which factors (cognitive, motor) the task depend on?

Methods

Participants:

16 trained pianists from Trieste Conservatory

Materials:

- 1) first 4 bars of Bach Prelude BWV 846
- 2) 6 audio files at 6 different tempi

Prelude No. 1 in C major, BWV 846
excerpt for psychological test
Johann Sebastian Bach

scale of tempi with **fixed frequency ratio** (in analogy with the well tempered scale of frequencies): **40.00, 47.57, 56.57, 67.27, 80.00, 95.14**

Example: 56.57 bpm 

Methods

Procedure:

2 experimental conditions:

- 1) participants performed at 3 different tempi: “tempo correct”, fast and slow; participants were divided in two groups: 8 Correct–Fast–Slow (CFS) and 8 Correct–Slow–Fast (CSF)

participants listened to their “tempo correct” performance and reproduced at the same tempo

participants listened to their “tempo correct” performance and reproduced at the double tempo

Methods

Procedure:

2 experimental conditions:

- 2) participants listened to audio files at 3 different metronomic tempi (random sequence of 3 stimuli selected among the 6 audio files) and reproduced at the same tempi

participants listened to audio files at 6 different metronomic tempi (random sequence different than the previous one) and reproduced at the double tempi

Data Analysis

- ✓ Choice of the optimal tempo
- ✓ Slowing down and speeding up
- ✓ Memory for musical tempo
- ✓ Reproducing a given tempo
- ✓ Doubling a given tempo

Optimal tempo:

Refs:

Bisesi & Vicario, 2010

McKinney & Moelants, 2004

Moelants, 2002

Our results:

$$T_{\text{mean}} = 64 \text{ bpm}$$

$$T_{\text{min}} = 50 \text{ bpm}$$

$$T_{\text{max}} = 77 \text{ bpm}$$

$$\sigma_t = 7.04 \text{ bpm}$$

Memory for musical tempo:

Refs:

Gratton & Bruno, in progress

Levitin & Cook, 1996

Experimental conditions:

(a) 8 subjects: target >> faster >> slower

[t, F1(=t*), S1]

(b) 8 subjects: target >> slower >> faster

[t, S2(=t*), F2]

Results:

The difference between faster and first target **is not** significantly different within the two experimental conditions

F1 – t vs. F2 – t:

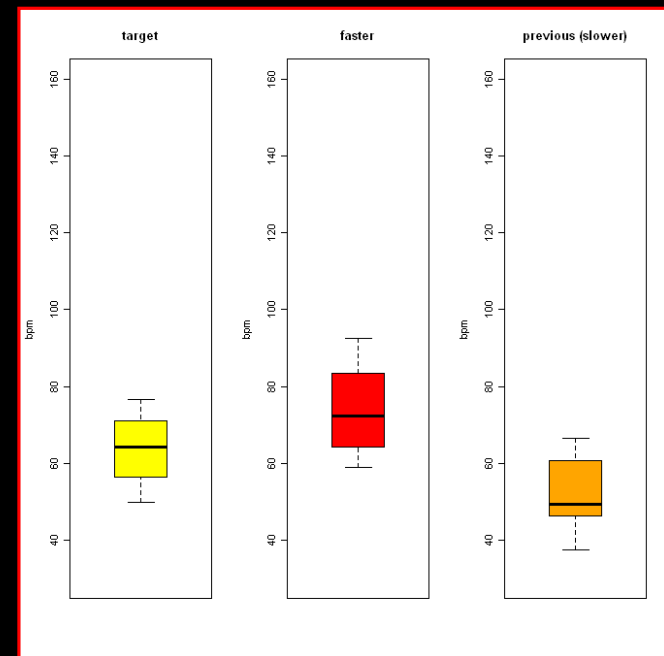

$t = -1.12$, $df = 7$, $p = 0.3$

The difference between faster and last target **is** significantly different within the two experimental conditions

F1 – t vs. F2 – t*(S2):

$t = -5.85$, $df = 7$, $p = 0.00063$

16/09/10

Results:

The difference between slower and first target **is not** significantly different within the two experimental conditions

S1 — t vs. S2 — t:

t = 0.17, df = 7, p = 0.87

The difference between slower and last target **is** significantly different within the two experimental conditions

S1 — t vs. S2 — t*(F2):

t = 5.0005, df = 7, p = 0.0016

**Memory for
musical tempo**

Results:

The difference between slower and first target **is not** significantly different within the two experimental conditions

S1 – t vs. S2 – t:

t = 0.17, df = 7, p = 0.87

The difference between slower and last target **is** significantly different within the two experimental conditions

S1 – t vs. S2 – t*(F2):

t = 5.0005, df = 7, p = 0.0016

Slow and fast are absolute concepts

Slowing down and speeding up:

Refs:

Krumhansl, 2000

Povel, 1981

Fraisse, 1982

Flach et al., 2004

Results:

Speeding up: 20.64 %

Min.	1st Qu.	Median	Mean	3rd Qu.	Max.	St.Dev.
58.96	70.31	75.23	76.26	81.35	99.68	10.92

Slowing down: 18.36%

Min.	1st Qu.	Median	Mean	3rd Qu.	Max.	St.Dev.
37.38	49.14	53.70	54.08	60.83	66.49	8.24

Results:

Faster: 20.64%

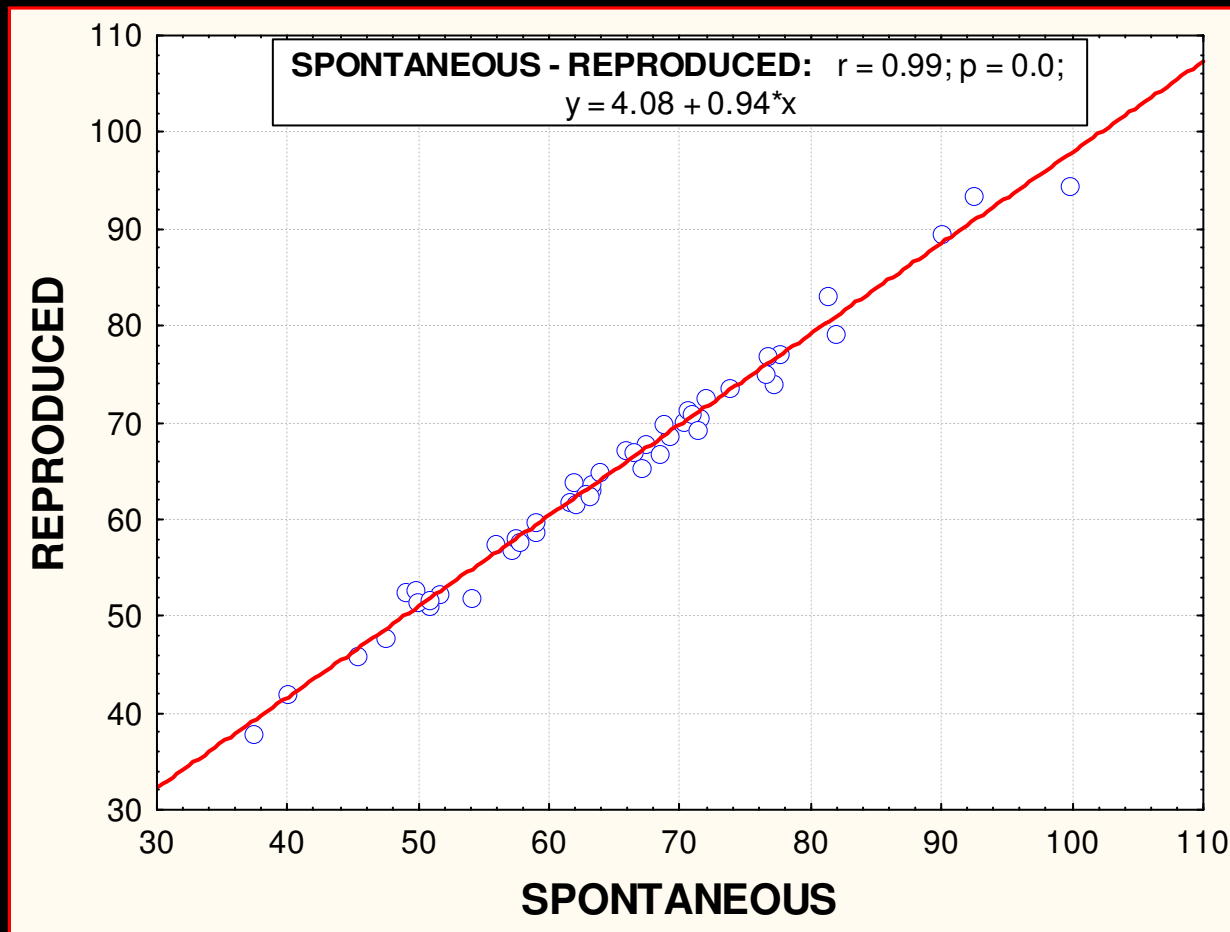

Slower: 18.36%

Double: 54.8 %

Reproduction of a given tempo

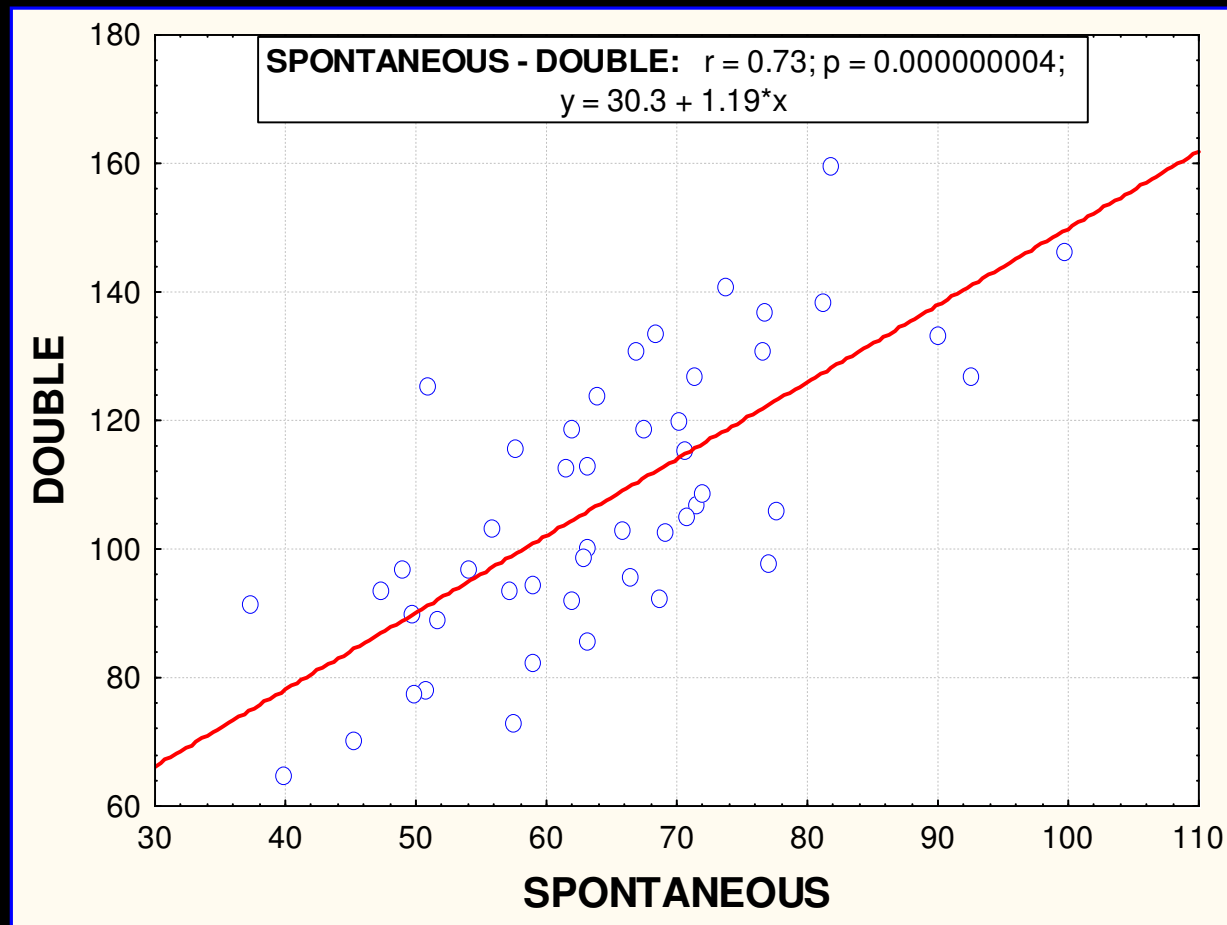

Exp 1:

**spontaneous
reproduction of
musical tempi
is homogeneous
along the whole
scale of speeds**

Reproduction of a given tempo

Exp 1:

reproduction at
a double tempo
is (less)
homogeneous
along the whole
scale of speeds

Reproduction of a given tempo

Exp 1:

reproduction at

double tempo
corresponds to
a constant shift

scale of speeds

Spontaneous vs. selected tempi:

Refs:

Shea et al., 2001

Schmidt, 1975

No task effect

(1) spontaneous:

$t = -1.41, df = 15, p = 0.18$

(2) double:

$t = -1.17, df = 15, p = 0.26$

Only 1 subject found difficulties in task (1)

General Linear Models:

Exp 1:

Effect	f	F	p
REPRODUCED	1	34.03	0
ID VEL	2	0.98	0.38

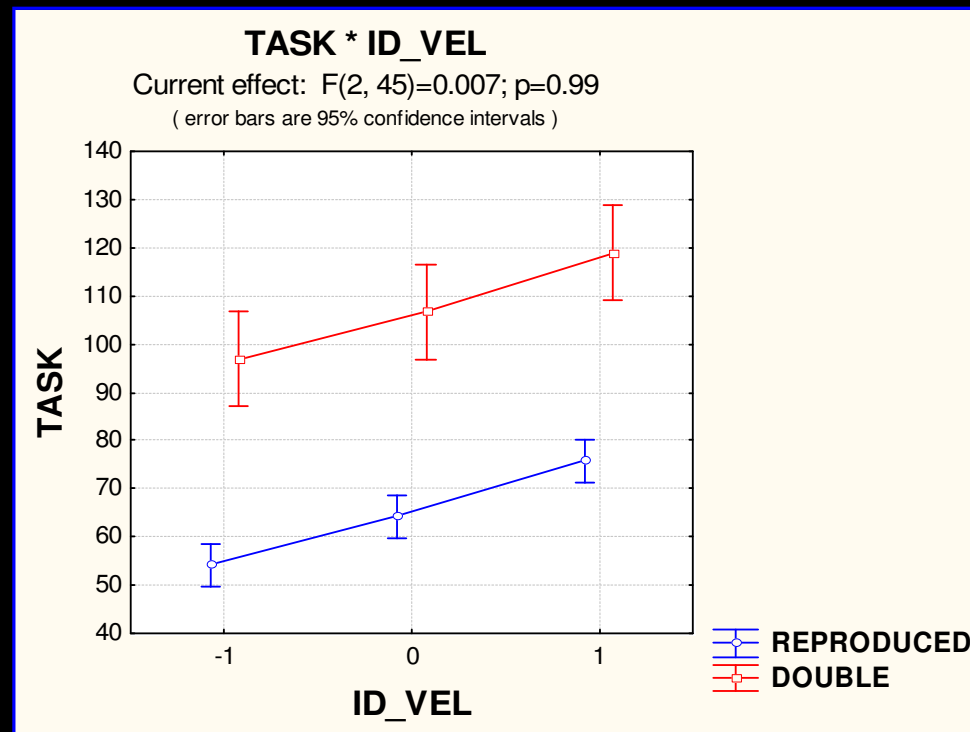

There is no constant modulation

Effect	f	F	p
SPONTANEOUS	1	166.9	0
TASK	1	5.7	0.02
TASK * SPONTANEOUS	1	2.4	0.13

There is an effect of SPONTANEOUS and TASK: subjects modulate according with spontaneous tempo

General Linear Models:

Exp 1:

Lines are parallel:

there is no interaction ($p=.131$ in previous table)

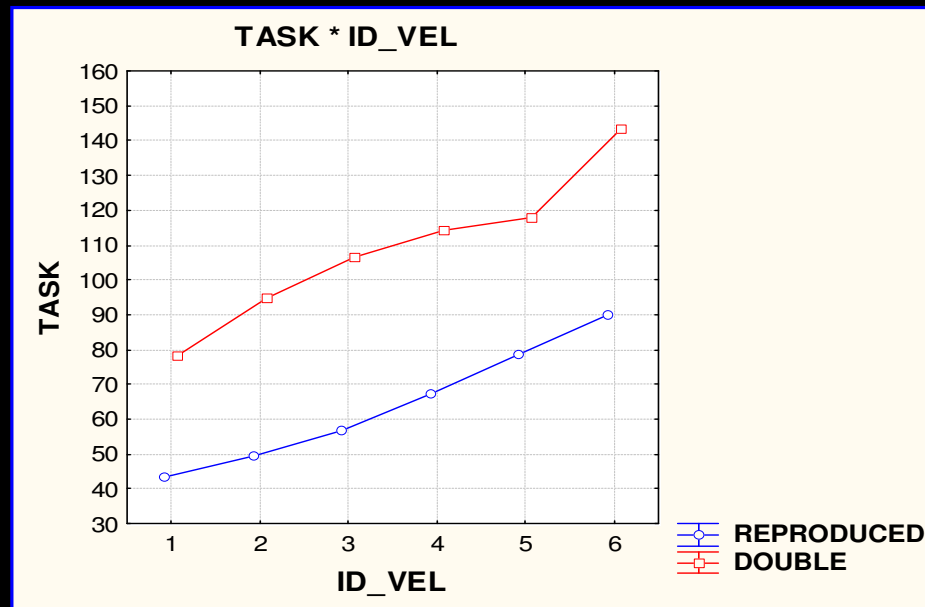

Spontaneous or doubled reproduction have the same behavior: once the slope due to spontaneous reproduction is left out, there is no task effect (reproduced, double)

General Linear Models:

Exp 2:

Effect	f	F	p
VEL	1	269.3	0
TASK	1	12.3	0.025
TASK * VEL	1	1.7	0.26
REP	7	0.7	0.70
REP * VEL	7	0.8	0.56
TASK * REP	7	0.8	0.63
TASK * REP * VEL	7	1.2	0.35

Task and velocity are both significant

double tempo
=
spontaneous tempo
+
a constant value

Conclusion

- Results support the conclusion of the existence of an “optimum” tempo
- Slow and fast are absolute concepts
- Participants exhibit a memory for musical tempo
- Spontaneous reproduction of musical tempi is homogeneous along the whole scale of speeds
- Double tempo corresponds to a constant shift

Improvements

- Confirm results with another experimental method (for instance, choice)
- Search for a correspondence inside other perceptual domains (visual, motor)
- Search for correlation with cognitive or motor competence

*"It is not that we have so little time,
but that we lose so much"*

Seneca

"Music is the best means we have of digesting time"

W. H. Auden
